

# ECCO Update

**GODAE OceanView Meeting, Paris, Nov., 14-18 2011**

**Tong (Tony) Lee**

**NASA Jet Propulsion Lab, California Institute of Technology**

## THE ECCO CONSORTIUM

ECCO was established in 1998 as part of the World Ocean Circulation Experiment (WOCE) and is focused on creating a comprehensive, integrated, and consistent data set in order to produce a high-quality, high-resolution ocean circulation and climate model. ECCO products are supported by numerous national and international organizations, such as the WMO's World Climate Research Programme (WCRP) and UNESCO's Intergovernmental Oceanographic Commission (IGO). These programs have collected a wide range of remotely-sensed and in-situ observations with known dynamics and thermodynamics through a GCM. ECCO products are in support of the Climate Variability and Predictability (CLIVAR) programme and the Global Ocean Data Assimilation Experiment (GODAE). [more](#)

## ECCO PRODUCTS

ECCO products as well as input fields and quality-controlled observations are freely available to the research community for various applications (including DODS/OPeNDAP, LAS, GDS, Dapper, SRB, Ingrid). [A summary of available ECCO products and data servers can be found here.](#)

## MIT GENERAL CIRCULATION MODEL

The ECCO code is based on the MIT general circulation model (MITgcm), a numerical model designed for simulation of the ocean and climate. It comes with a variety of packages including physical parameterizations, a sea-ice model, biochemical components, and allows flexible porting across various HPC platforms. [For more details on the MITgcm click here.](#)

## MIT AUTOMATIC/ALGORITHMIC DIFFERENTIATION (AD)

Since the mid-1990's, groups at MIT, SIO, JPL and GFDL have applied automatic/algorithmic differentiation (AD) to the MITgcm. This has allowed the development of efficient linear and adjoint code for ocean circulation and climate studies. ECCO relies heavily on the AD tool TAMC and its commercial successor TAF. The ECCO group is also involved in the development of a new open-source AD tool, OpenAD. [More details can be found here.](#)

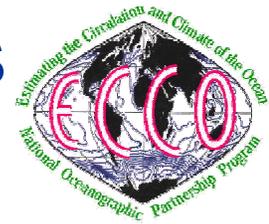

National Oceanographic Partnership Program

Main partners: JPL, MIT, AER, SIO, Univ. Hamburg

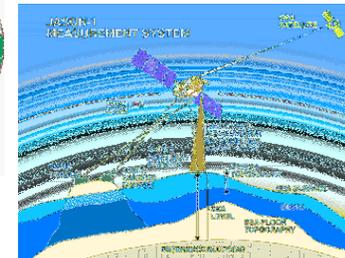

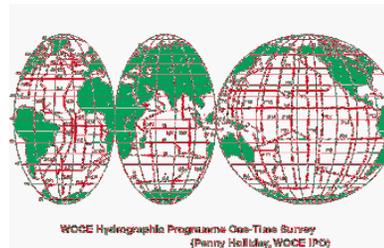

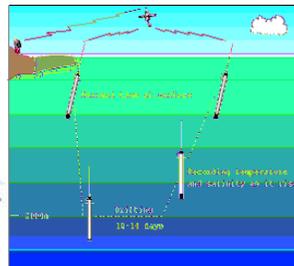

# ECCO Global Ocean-Sea Ice Synthesis

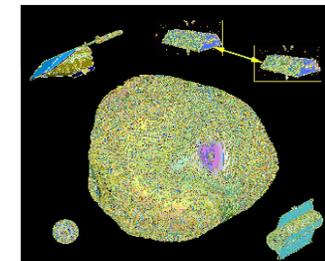

- Assimilate a diverse sets of satellite and in-situ observations using inverse methods.
- Ocean state estimation products from 1992 onward, extended routinely (1950-2001 for G-ECCO)
- Mainly gear towards climate & biogeochemistry applications

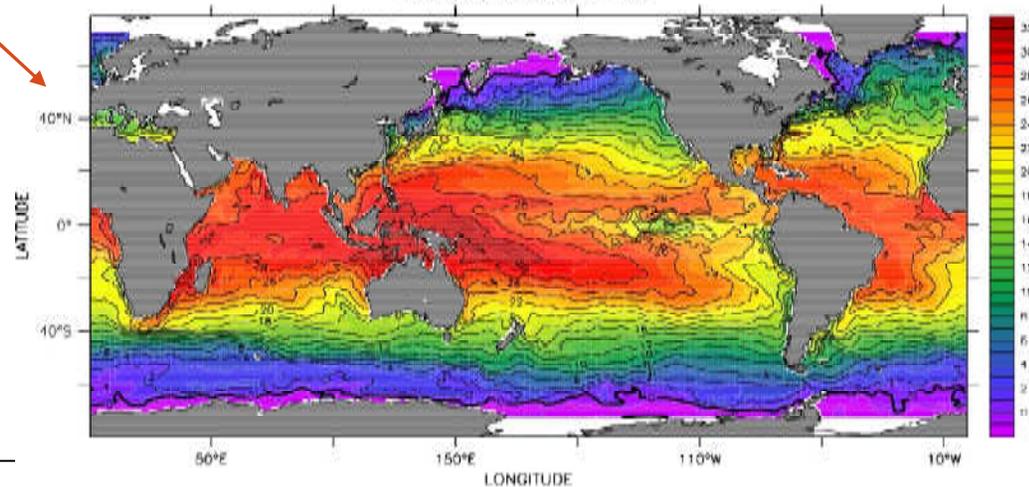

In-situ observations

Satellite data

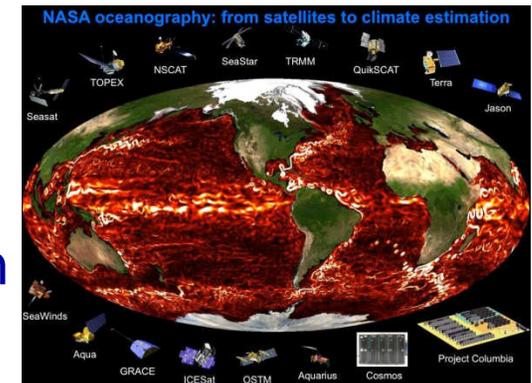

Assimilation (Adjoint) by ODAP

# From Global to Regional Estimation

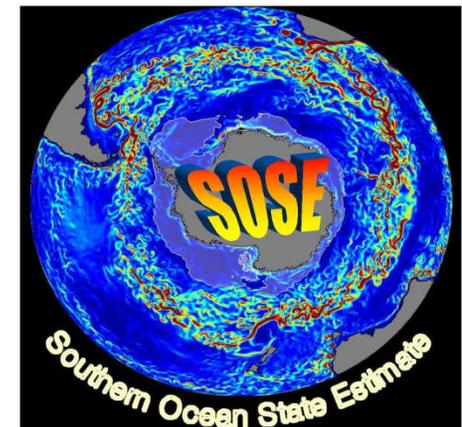

Global: (1° to 18 km, 23 to 50 levels)

- Core effort: ECCO Central Solution – a.k.a. ECCO-CLIVAR (adjoint)
- ECCO-JPL near realtime estimation (Kalman filter & smoother)
- ECCO2/3 eddy-permitting estimation (Green's function, adjoint)
- G-ECCO (adjoint, five decades)

Regional (downscaling):

- Southern Ocean
- Tropical Pacific
- Gulf of Mexico
- California Current System

# ECCO Central Solution: observations (Table 1) & Key Attributes (Table 2)

Table 1

Variable	Source (Duration) / Reference (Year)
Sea level	TOPEX/Poseidon, Jason-1 & -2 (1992-2010), <i>Geosat-Follow-On</i> (2001-2005), ERS-1/2 (1992-2001), ENVISAT (2002-2008), <i>tide gauges</i> (1992-2010)
climatology (T&S)	Gouretski and Koltermann (2004)
Temperature	CTDs (1992-2010), XBTs (1992-2010), Argo floats (1997-2010), <i>TOGA/TAO+PIRATA moorings</i> (1992-2010), <i>Southern Elephant seals as Oceanographic Samplers (SEaOS; 2006-2008)</i> , <i>RAPID moorings</i> (2004-2010)
Salinity	CTDs (1992-2010), Argo floats (1997-2010), <i>SEaOS</i> (2006-2008)
SST	AVHRR (1992-2010), TMI (1998-2010), AMSR-E (2002-2010)
Sea surface salinity	thermosalinographs (Etudes Climatiques de l'Océan Pacifique, 1992-1999)
Key transports	<i>Florida Strait transport</i> (1992-2010)
Sea ice concentration	<i>SSM/I</i> (1992-2010)
Time-mean SSH	GRACE (2002-2010), altimetry (1992-present)
Ocean bott. press.	<i>GRACE</i> (2002-2010)
Wind stress	<i>NSCAT</i> (1996-1997), <i>QuikSCAT</i> (1999-2008), ERS-1/2 (1992-2001)

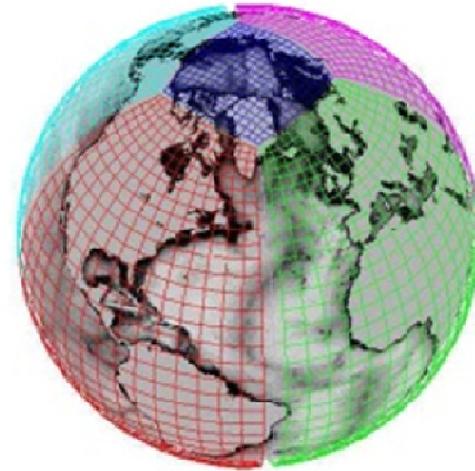

Table 2

	In data server	In production	Upcoming	
Attribute	V2	V3	V4	NRT
Synthesis method	adjoint	adjoint	adjoint	<i>RTS smoother</i>
Period	1992-2004	1992- <i>2010</i>	1992- <i>present</i>	1992- <i>present</i>
Observations	Table 1	<i>Table 1</i>	<i>Table 1</i>	<i>sea level &amp; T profiles</i>
Model domain (horiz. Resolution/vert. levels/extent)	1°/23/80°S~80°N	1°/23/80°S~80°N	1°/23/90°S~90°N	<i>0.3°~1°/46/80°S~79°N</i>

# Version 4 of ECCO Central Solution

- Inclusion of the Arctic Ocean
- Prognostic sea ice model & its adjoint
- Inclusion of mixing parameters as control

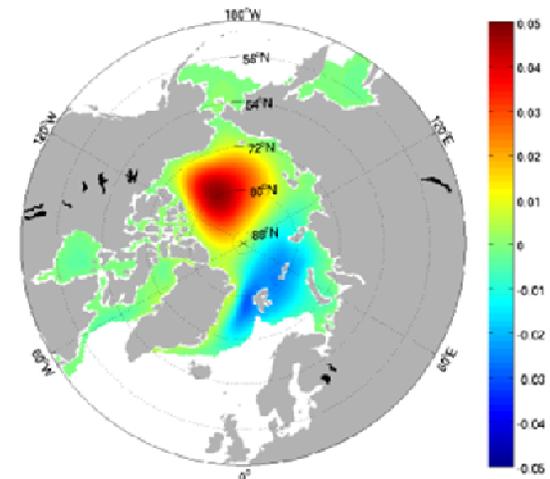

Global grid

Estimated time-mean global MOC

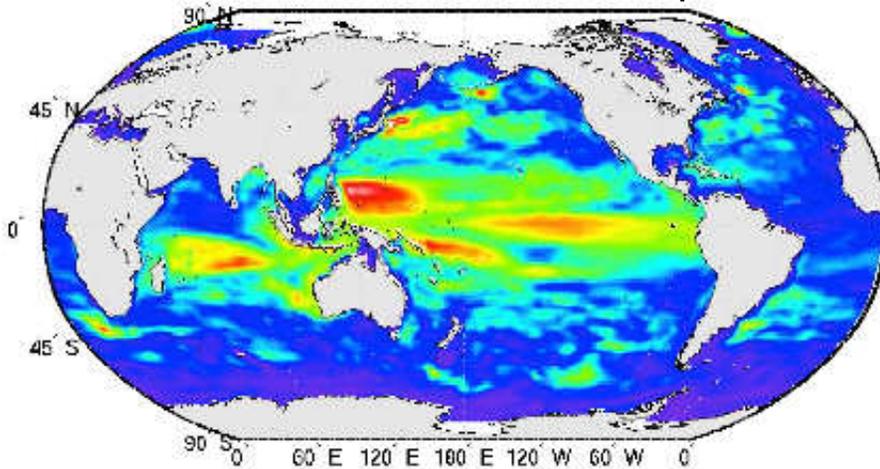

Estimated sea ice circulation

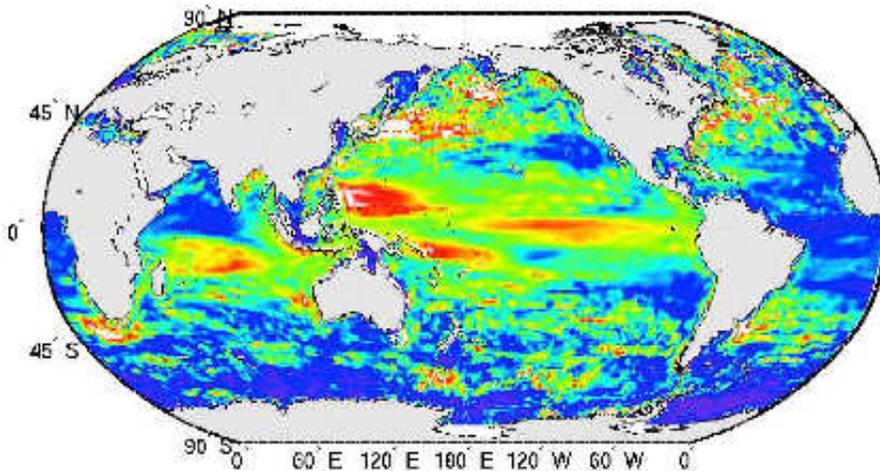

# Understanding sea level budget: wind-forced variability

## Total Variability $\zeta_{\rho}^W$

## Advective Transport $A^W$

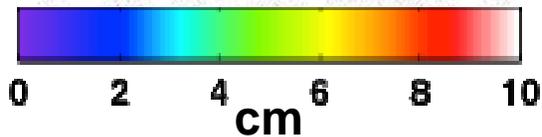

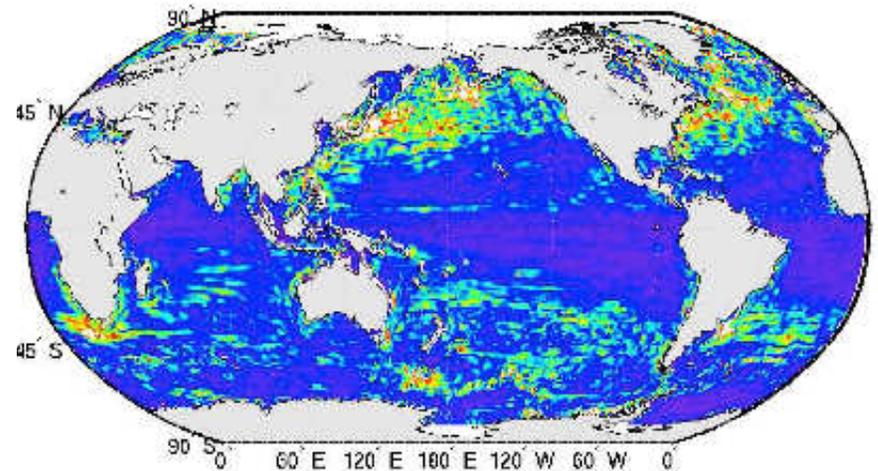

## Steric height budget:

$$\zeta_{\rho} = A + M + F$$

Piecuch & Ponte (2011) GRL 38

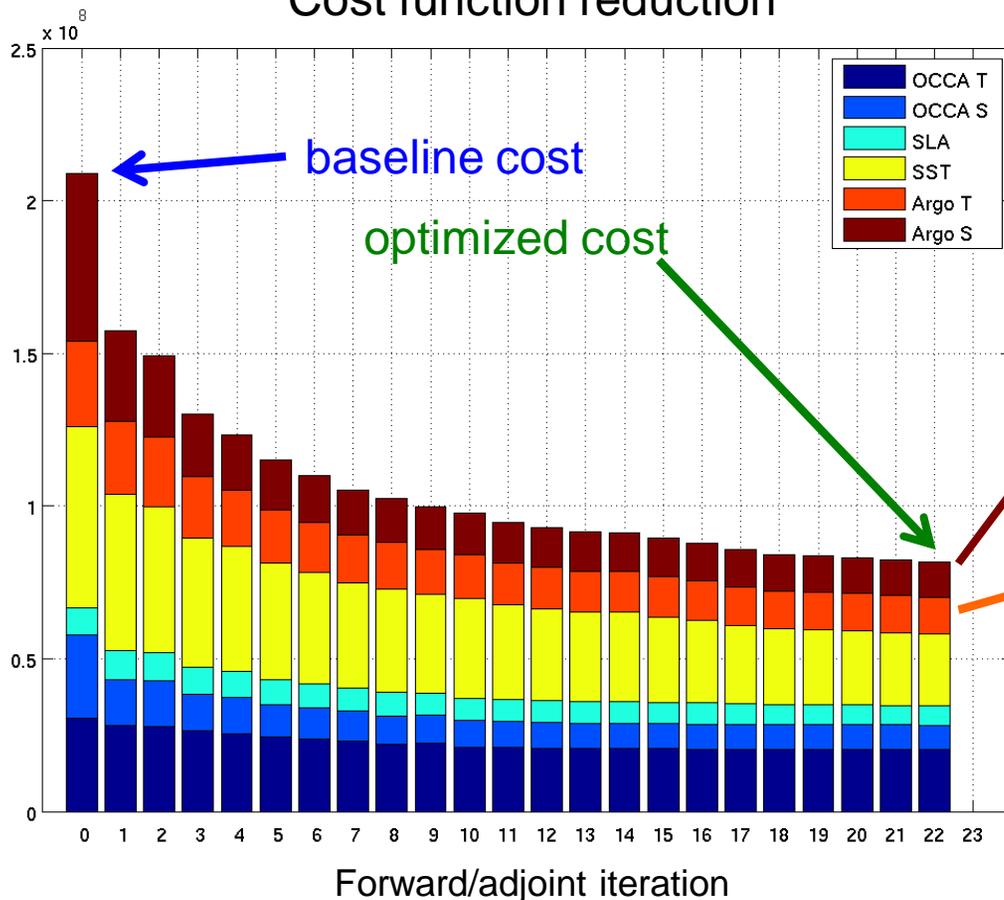

## Diffusive Transport $M^W$

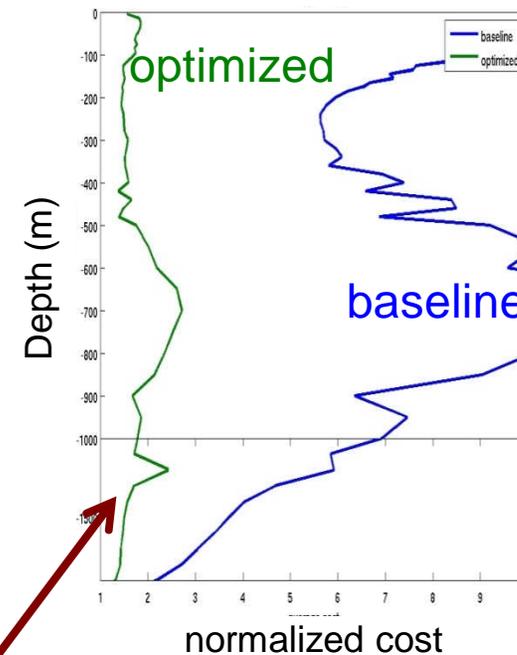

# ECCO2 adjoint-based optimization of an eddy global-ocean & sea ice MITgcm configuration

- Data constraints currently include JASON SLA, AMSR-E SST, ARGO T/S profiles, and OCCA T/S climatology.
- Control variables are initial T/S and atmospheric boundary conditions (wind, precipitation, air temperature and humidity, incoming radiation)

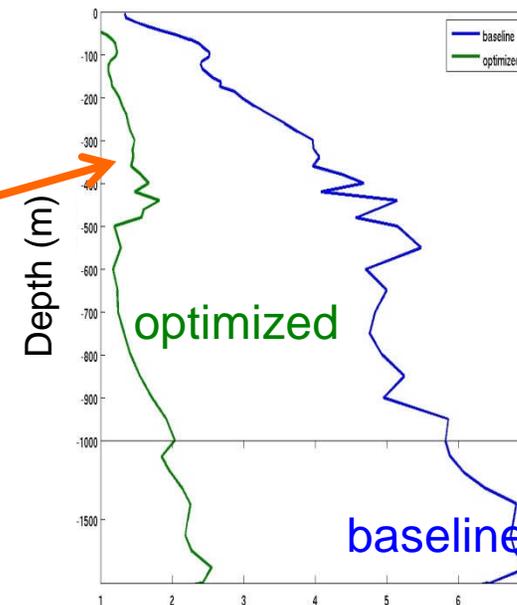

## Cost function reduction

## ARGO S cost reduction

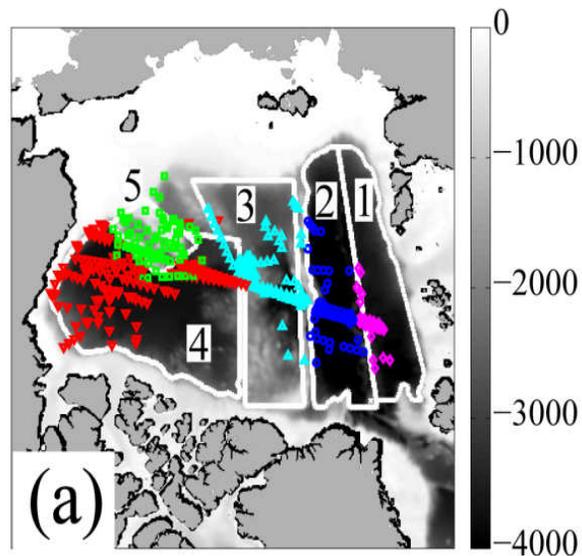

## ARGO T cost reduction

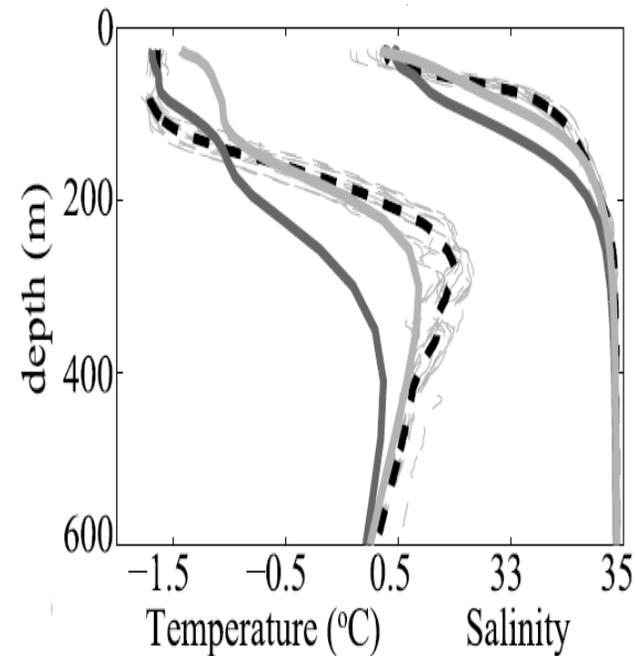

# Salt-plume parameterization in ECCO2 improves representation of the Arctic halocline

Arctic hydrographic stations

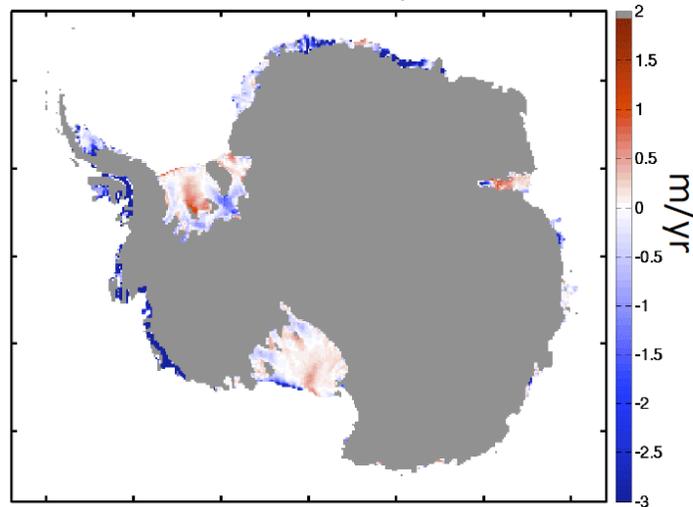

- ■ ■ Observations
- Baseline simulation
- With plume parameterization

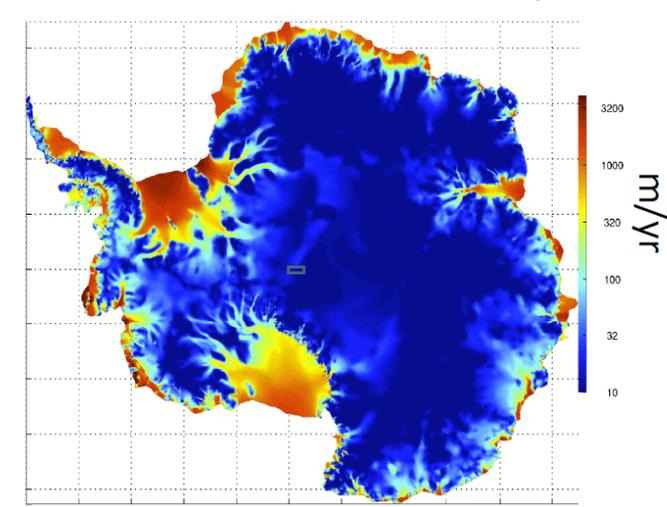

(Nguyen, Menemenlis, and Kwok, 2009)

## Toward coupled ocean, land ice simulations

a) ECCO2 ice shelf cavity melt rate

b) ISSM land ice surface velocity

- The interaction between ocean and ice sheets on rather small scales, that is, in sub-ice shelf cavities around Antarctica and in narrow fjords around Greenland, may provide a key link between observed accelerated glacier flow and large scale oceanic variability and circulation changes.
  - Critical processes on the oceanic side include topographic steering, eddy variability, tidal mixing, and brine rejection by sea ice.
  - For ice sheets, critical processes include grounding line migration and higher-order stress coupling.
  - Faithful representation of these ocean/ice-sheet interactions thus emerges as a new frontier for Earth System Models and it may well be the key ingredient in any coupled modeling effort that attempts to quantify and reduce uncertainties in sea level rise projections for the next century.
-

# Adjoint sensitivities of sub-ice shelf melt rates to ocean circulation under Pine Island Ice Shelf, West Antarctica

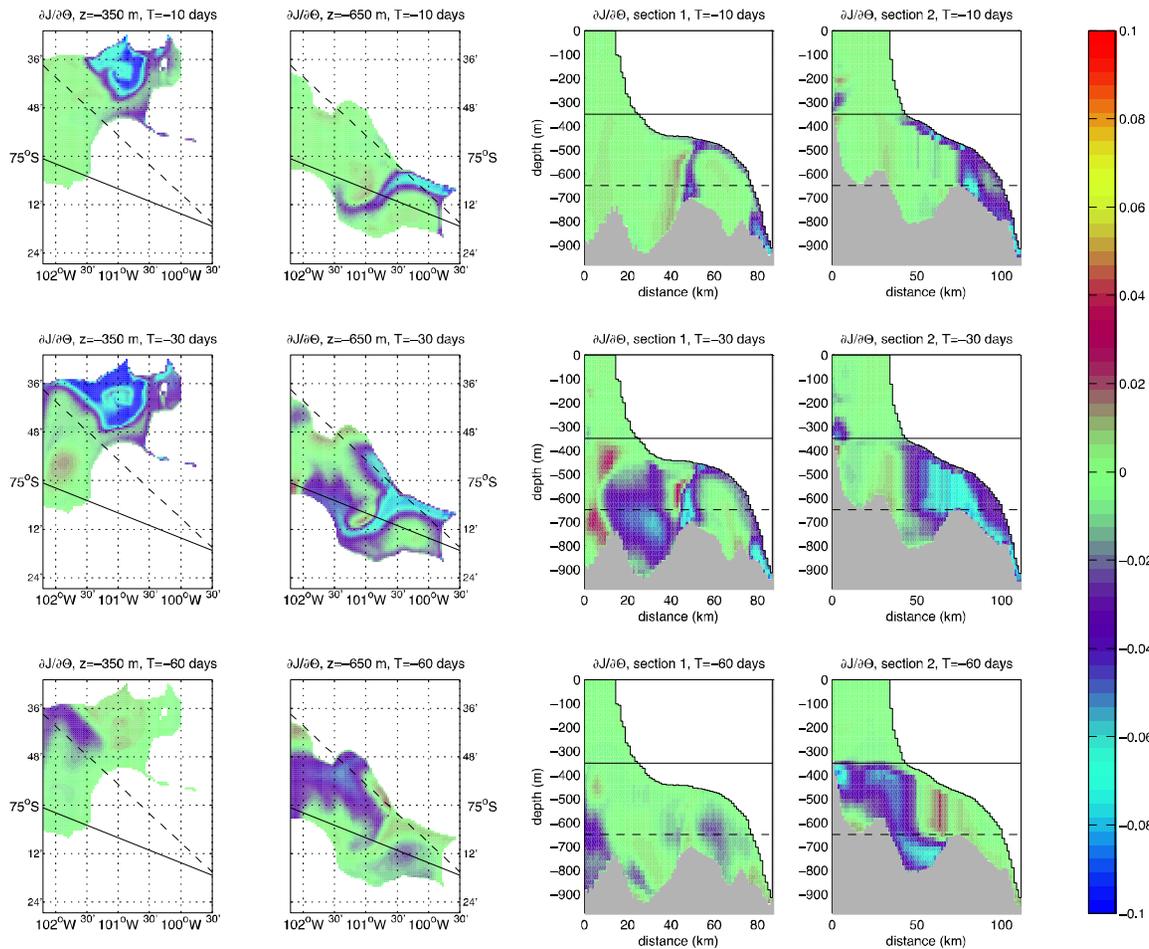

Fig. 4. Adjoint sensitivities  $\delta^*T = (\partial J \partial T)^T$  at  $t = \tau_f - 10$  days,  $-30$  days, and  $-60$  days. Horizontal slices at  $z = -350$  m and  $z = -650$  m on the left hand side, vertical sections on the right hand side. The solid lines in the horizontal slice plots indicate section 1 (right-center), and the dashed lines section 2 (far right). The solid and dashed lines in the vertical section plots indicate the positions of the horizontal slices. Units are in  $\text{m}^3 \text{s}^{-1} \text{K}^{-1}$ ,  $0.1 \text{ m}^3 \text{s}^{-1} \text{K}^{-1} \approx 3 \text{ Mt a}^{-1} \text{K}^{-1} \approx 3 \text{ mm a}^{-1} \text{K}^{-1}$ .

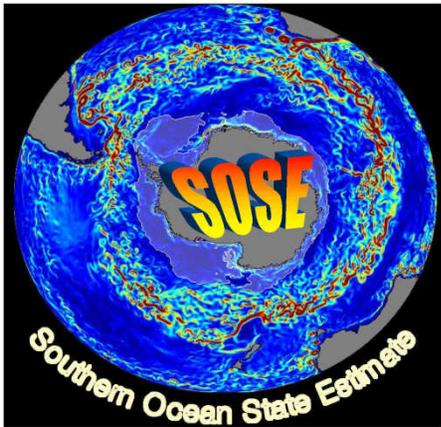

Heimbach and Losch have developed an adjoint model for the MITgcm ice shelf cavity model.

As a first demonstration of this new capability, they investigated the sensitivity of sub-ice shelf melt rates to changes in the oceanic state.

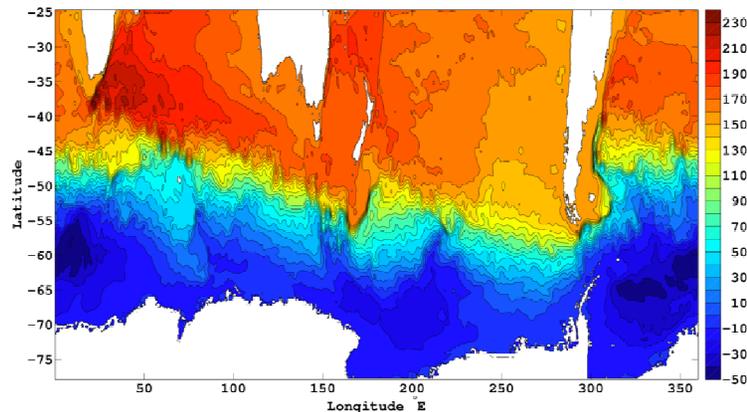

The inferred sensitivities reveal a dominant time scale of roughly 60 days over which the shelf exit is connected to the deep interior.

To the extent that these transient patterns are robust they carry important information for decision-making in observation deployment and monitoring.

(Heimbach and Losch, submitted)

- Domain: 78° South to 24.7° South
- 1/6°, 42 depth levels (partial cells)
- Initial and northern boundary conditions derived from and constrained to G. Forget's (2010) 1° resolution global state estimate (OCCA).
- Full (and adjointable) coupled sea-ice model

Vertically integrated  
(barotropic) transport  
streamfunction [Sv] (2005-  
2006 average)

### Southern Ocean State Estimation

A modern general circulation model, the MITgcm, is least squares fit to all available ocean observations. This is accomplished iteratively through the adjoint method. The result is a physically realistic estimate of the ocean state. SOSE is being produced by Matthew Mazloff as part of the ECCO consortium and funded by the National Science Foundation. Computational resources are provided in part by the NSF TeraGrid.

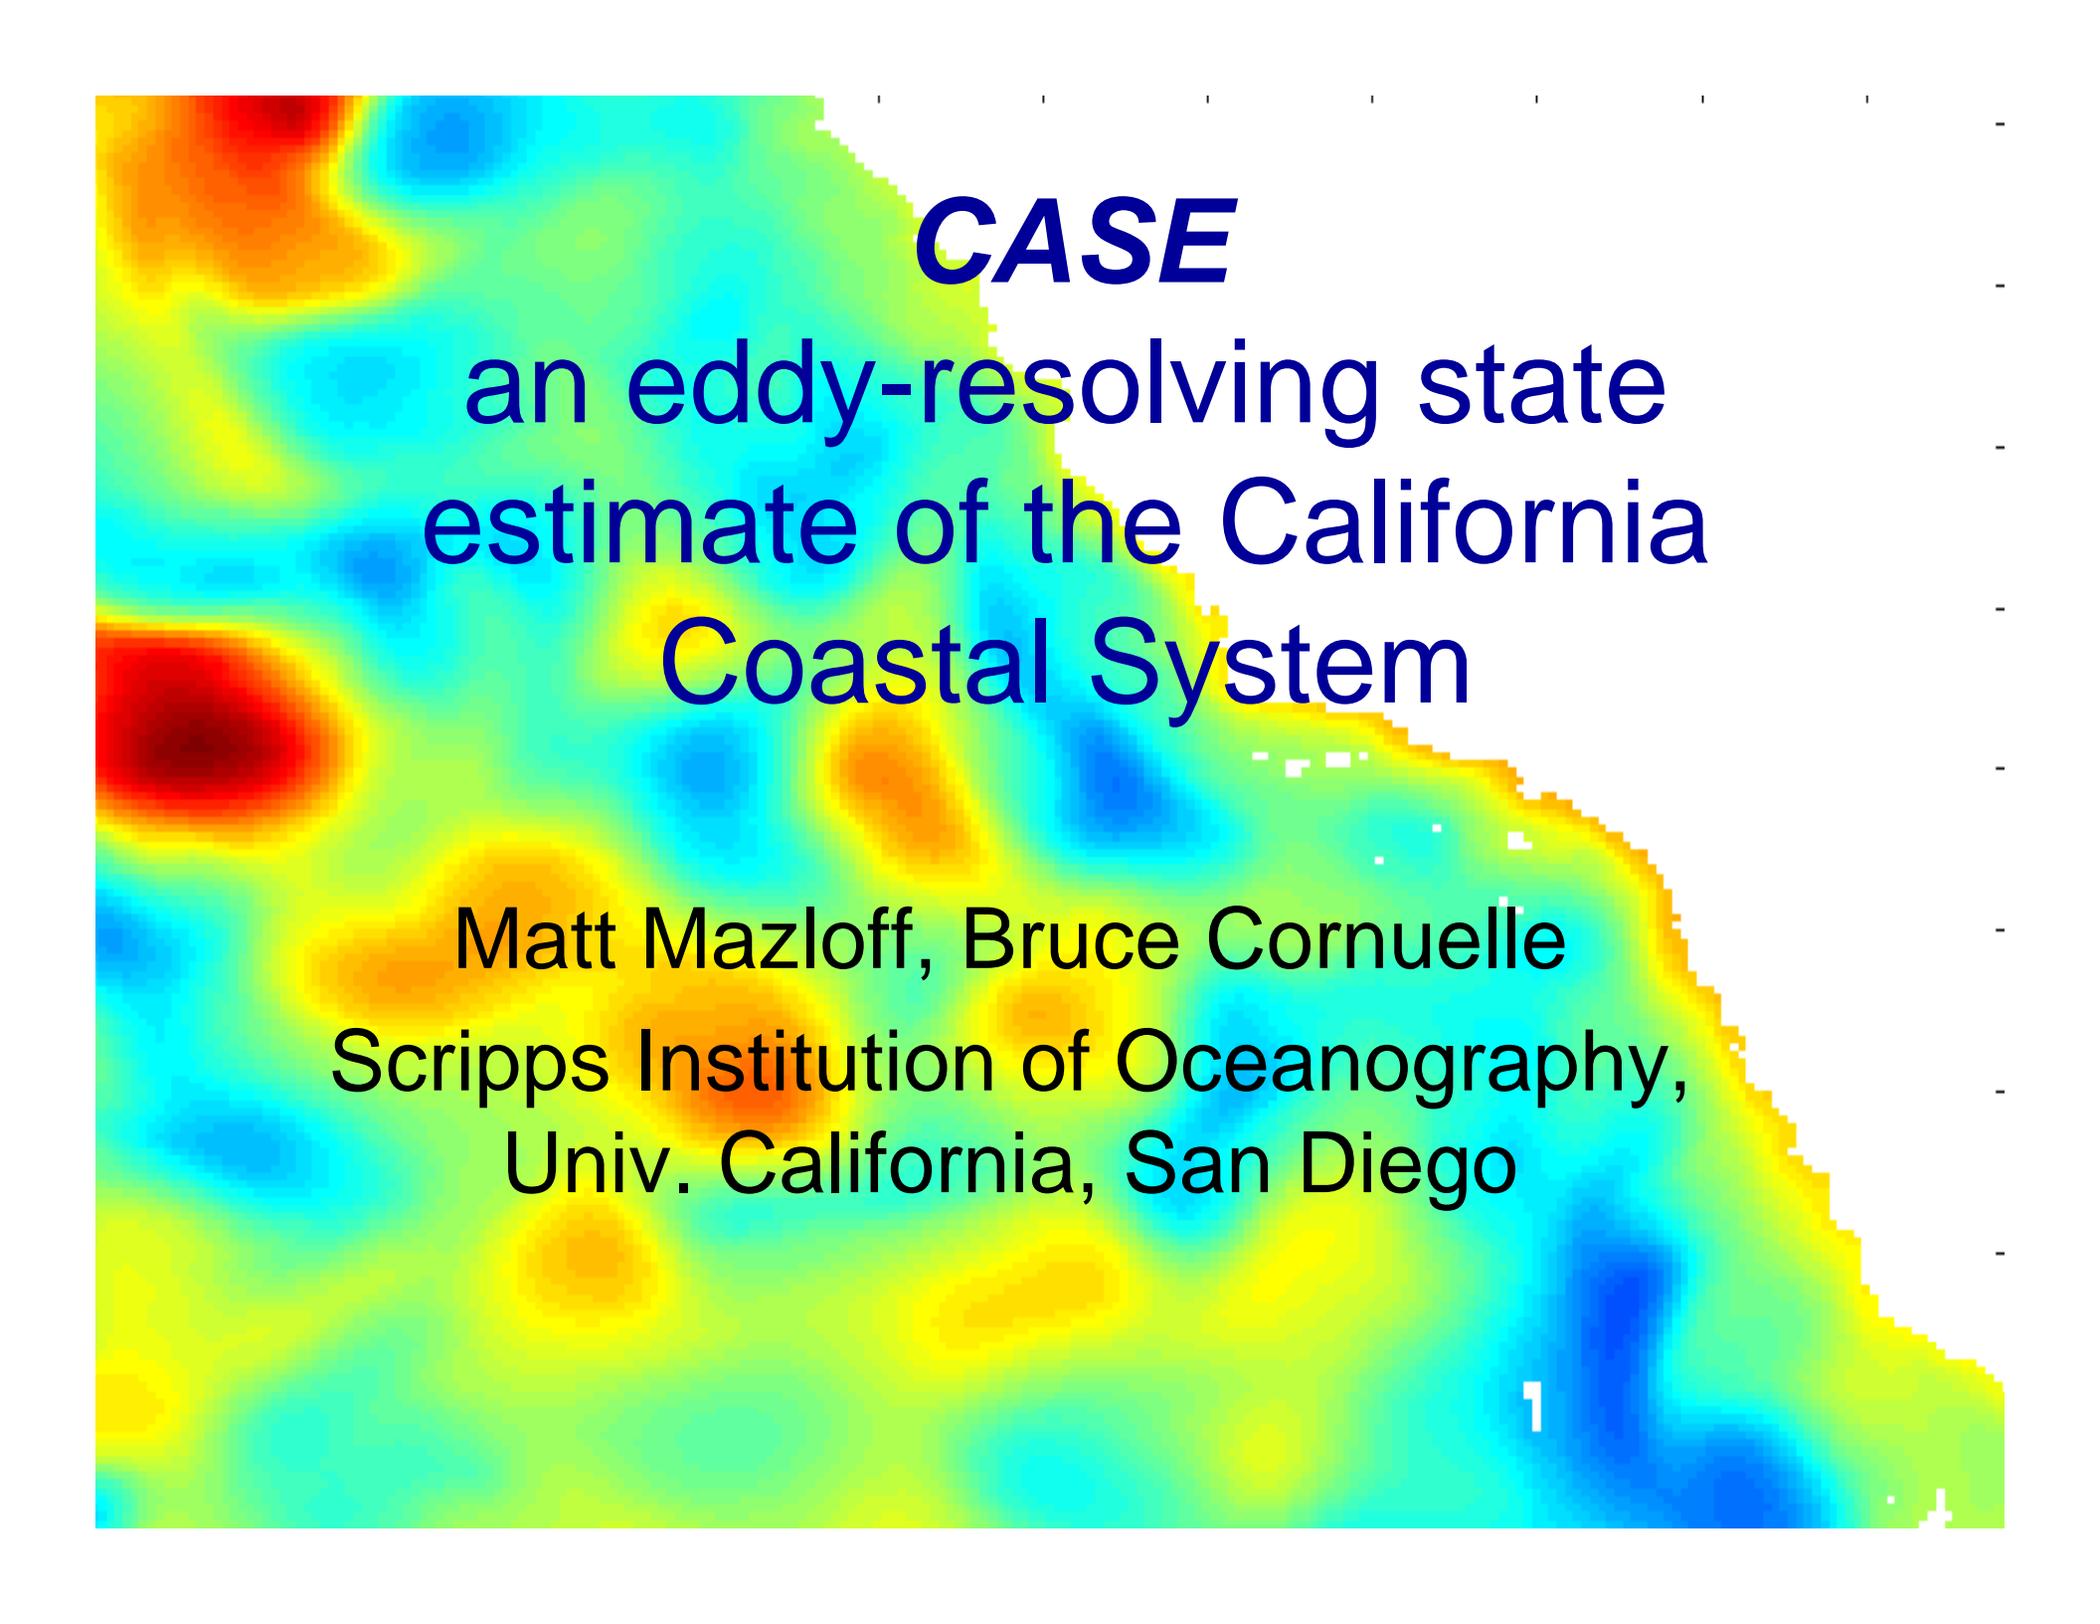

For more information on the adjoint method see C. Wunsch and P. Heimbach, 2007: "Practical Global Oceanic State Estimation." *Physica D*. (pdf)

For more information on SOSE see M. Mazloff, P. Heimbach, and C. Wunsch, 2010: "An Eddy-Permitting Southern Ocean State Estimate." *J. Phys. Oceanogr.*, 40, 880–899. doi: 10.1175/2009JPO4236.1

You are encouraged to use our results, but please be aware of the [disclaimer and terms of use](#). Some data are preliminary and may not be suited to your needs.

## ECCO2 estimates of basal melting

Freshwater flux (**59 mSv** or **1600 Gt/a**) is double previous (BRIOS) estimates, more consistent with mass loss derived from ICESat/GLAS data (**55 mSv**), comparable in size with iceberg calving (**2000 Gt/a**).

## Antarctic Bottom Water formation

Freshwater input from basal melt decreases High Salinity Shelf Water production, which affects Antarctic Bottom Water production and meridional overturning.

## Coupling with ISSM

Experimental coupling with JPL/UCI ISSM is underway for improved estimates of ice shelf-ocean boundary conditions.

Mean Melt Rate  $dh/dt$  [m/a]
